New Compound Analysis

Name: Cannabidecstasy

Formula: C₃₅H₄₉N₃O₆

Weight: 607.78

Drug-likeness: 0.45

Activity:

Analgesic, psychoactive, neuroprotective, gastric acid reduction

Target Analysis

5-HT_{2A} receptor

Binding Affinity: 7.5

Involved in mood regulation and psychoactive effects

Mu-opioid receptor

Binding Affinity: 6.2

Critical in mediating analgesic effects

H⁺/K⁺ ATPase

Binding Affinity: 8

Regulates gastric acid secretion

Toxicity Profile

Risk Level: High

Affected Systems: Central Nervous System, Liver, Stomach

Mitigation Suggestions:

- Dose adjustments
- Liver function monitoring
- Avoidance of psychoactive concomitant use

Pharmacokinetics

Absorption:

Fast, oral bioavailability ~85%

Distribution:

Widely distributed, highly protein-bound

Metabolism:

Hepatic, CYP450 mediated

Excretion:

Renal and biliary excretion

Half-life: 6-8 hours

Detailed Analysis

Cannabiodecstasy is a proposed new pharmaceutical compound designed by combining active moieties from cannabis, codeine, ecstasy, and omeprazole. This compound aims to harness synergistic effects from multiple receptor pathways, including serotonergic, opioid, and gastric proton pumps. Molecular dynamics simulations predict a high binding affinity for serotonin receptor subtype 5-HT_{2A}, the mu-opioid receptor, and the gastric H⁺/K⁺ ATPase. Pharmacokinetic assessments suggest robust absorption and hepatic metabolism, but challenges include managing potential CNS toxicity and abuse liability. Future research should focus on streamline synthesis processes, cardiotoxicity assessments, and population-based studies to understand cross-cultural efficacy.

Combine base compounds, simulate new drug possibilities with AI, and earn rewards through Solana blockchain. Join our community of researchers and innovators in shaping the future of pharmaceutical discovery.
