New Compound Analysis

Name: MethaPhencyl

Formula: C17H23N

Weight: 241.38

Drug-likeness: 0.5

Activity:

Psychoactive Stimulant

Target Analysis

Dopamine Transporter

Binding Affinity: -9

Involved in dopamine reuptake inhibition facilitating increased dopamine levels

NMDA Receptor

Binding Affinity: -7.5

NMDA receptor antagonism contributes to dissociative effects

Toxicity Profile

Risk Level: High

Affected Systems: Brain, Heart

Mitigation Suggestions:

- Reduced dosage regimens
- Regular cardiac monitoring

Pharmacokinetics

Absorption:

Rapidly absorbed through oral and intravenous routes

Distribution:

Widely distributed, crosses blood-brain barrier

Metabolism:

Primarily hepatic, involving CYP450 enzymes

Excretion:

Renal, as both parent compound and metabolites

Half-life: 10-12 hours

Detailed Analysis

MethaPhencyl is a hypothetical compound designed by amalgamating active moieties of Methamphetamine and PCP. It showcases psychoactive stimulant properties with dual action on dopamine transporters and NMDA receptors, making it a candidate for psychoactivity and dissociative states. Despite potential applications in treatment-resistant depression, its high toxicity levels, primarily affecting the brain and heart, raise significant safety concerns. Pharmacokinetically, it is adept at crossing the blood-brain barrier, rapidly metabolized hepatically. Our research hypothesis focuses on leveraging its CNS activity for neurological disorder treatment, albeit necessitating extensive studies to mitigate its addictive and toxic potentials.

Combine base compounds, simulate new drug possibilities with AI, and earn rewards through Solana blockchain. Join our community of researchers and innovators in shaping the future of pharmaceutical discovery.
